Catalysis with Nanoparticles II

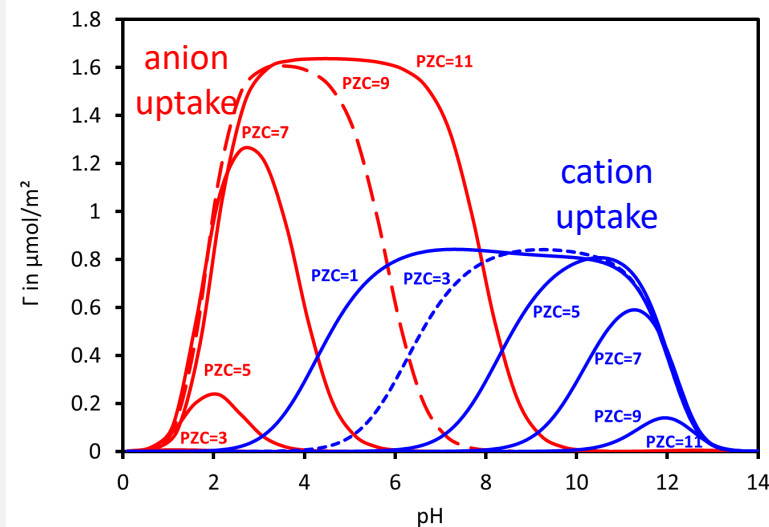

27 June 2019

INTRODUCTION: STRONG ELECTROSTATIC ADSORPTION (SEA)

- Inducing surface charge on support by adjusting pH of impregnating solution
- SEA at incipient wetness is also called Charge Enhanced Dry Impregnation (CEDI)

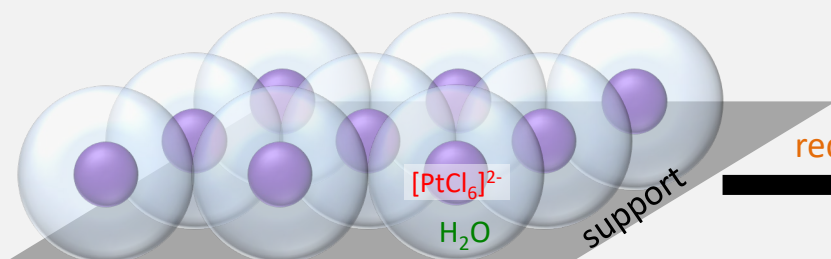

metal uptake (per support area)

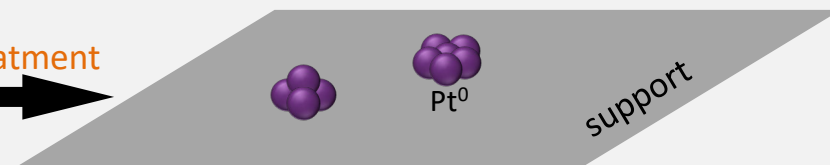

pH < PZC

@ PZC

pH > PZC

reduction treatment

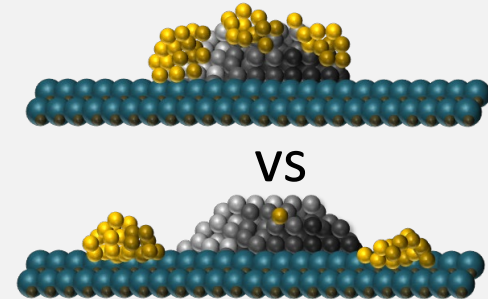

- resulting close packed monolayer of ionic complex (retaining hydration sheaths) with **strong interaction** with support

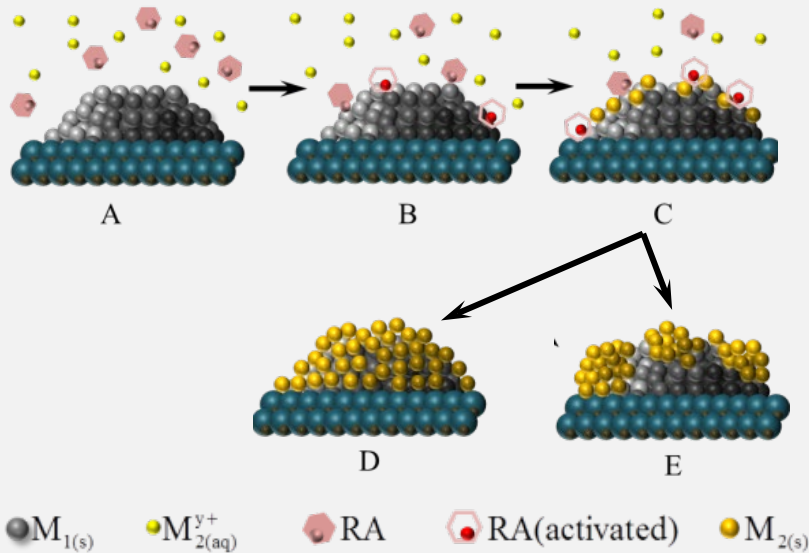

- decreased mobility of metal atoms result in smaller catalyst particles (compared to simple impregnation)

INTRODUCTION: ELECTROLESS DEPOSITION (ED) FOR BIMETALLIC CATALYSTS

- Addition of another metal can enhance catalytic activity through bimetallic effects: bifunctional, electronic, and/or ensemble.
- Usual method of co-impregnation does not ensure interaction between component metals

ED: Controlled deposition of secondary metal on the surface of primary/seed catalyst

- A) Immersion of seed catalyst in ED bath
- B) Activation of reducing agent (RA) on the surface of seed catalyst
- C) Reduction and deposition of secondary metal
- D) Catalytic deposition
- E) Auto-catalytic deposition

- Necessary to have proper combination of reducing agent, metal precursor, and ED conditions

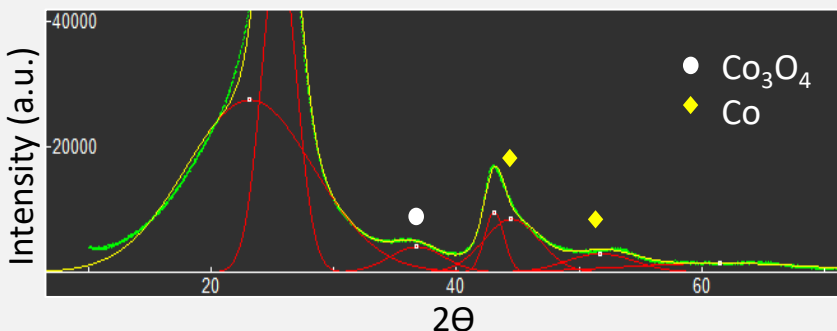

PRIOR WORK: BATCH ED OF PLATINUM ON CARBON SUPPORTED COBALT

Base catalyst made by modified CEDI

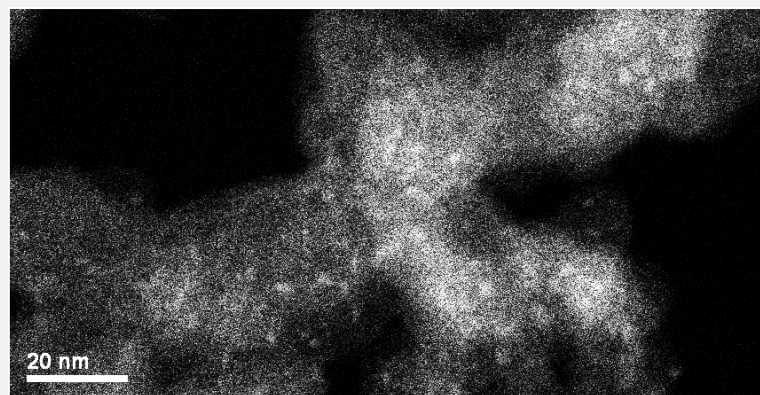

Impregnation of Cobalt nitrate with Citric acid on Carbon Acethylene Black (**CB1**, PZC=3.4)

Annealing in He at 250°C for 4hrs, Reduction at 400°C for 1hr

Representative XRD profile of 2.5% Co/CB1

HAADF-STEM micrograph of 5% Co/CB1

Electroless Deposition in Batch Mode

Reducing Agent: Dimethylamineborane (DMAB)

Pt Precursor: Chloroplatinic acid, H₂PtCl₆

pH condition: basic – pH 10, above PZC of carbon support (3.7), to prevent adsorption of [PtCl₆]²⁻ on carbon surface

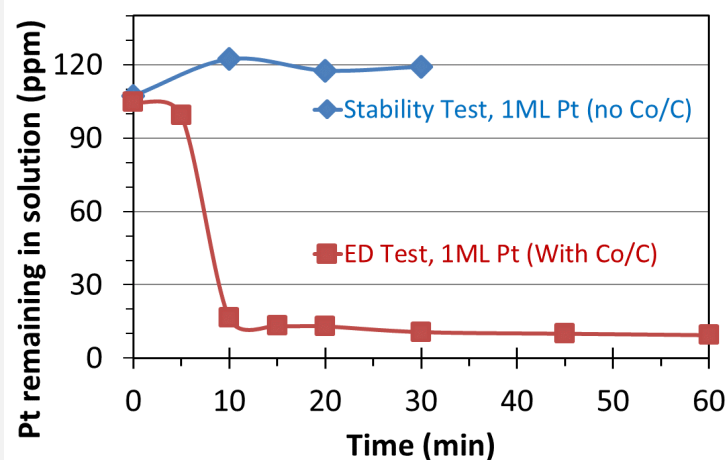

Ethylenediamine added to improve bath stability

Pt:DMAB:EN = 1:5:4

T = 50°C

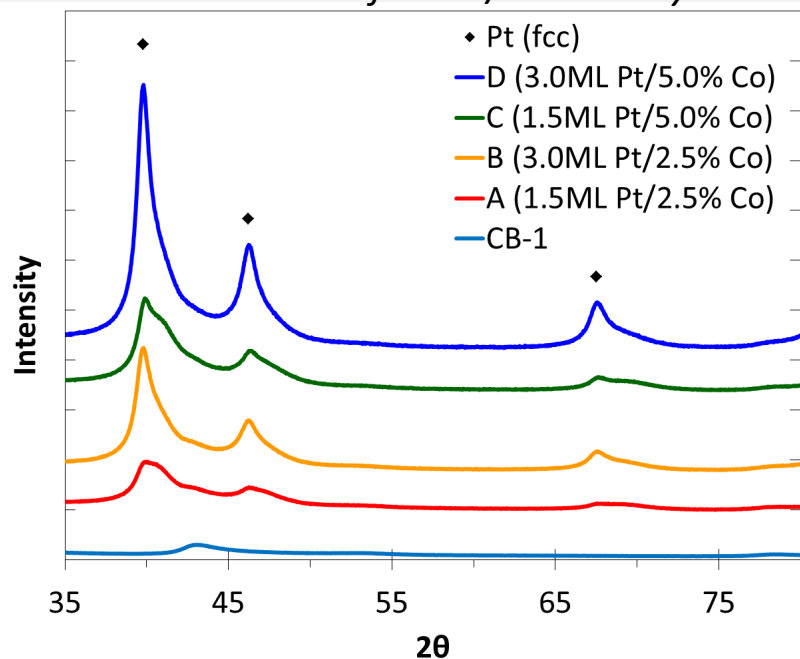

Theoretical Pt coverages used: 1.5ML, 3.0ML

Trial deposition curves – Pt ED on Co/CB1

PRIOR WORK: BATCH ED OF PLATINUM ON CARBON SUPPORTED COBALT

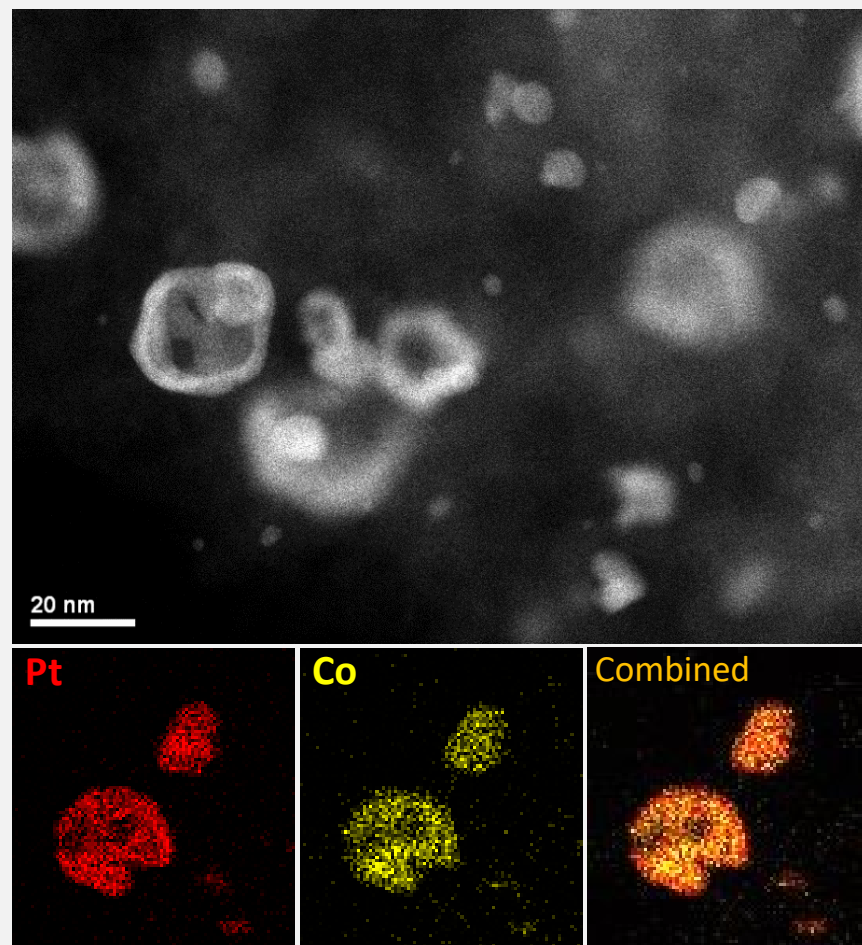

XRD Patterns of Pt-Co/CB1 Catalysts

Catalyst	Pt wt%	Co wt %	Bulk atomic Pt/Co	Alloy Lattice Param. (Å)
A	6.7	0.9	2.34	3.85
B	12.2	1.2	3.10	3.87
C	12.6	2.4	1.60	3.85
D	22.2	2.6	2.55	3.88
Pt				3.92
Co				3.55

Representative Micrographs and Maps of Pt-Co/CB1

3.0ML Pt - 5.0% Cobalt on Carbon Black, reduced 200°C, 1 hr

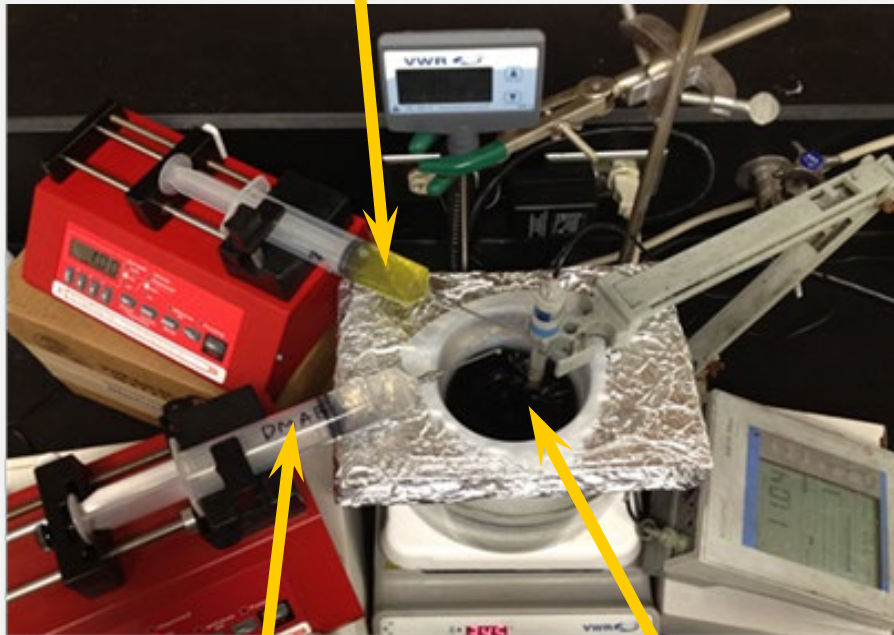

- Shoulders to the right of Pt XRD peaks indicate alloy formation.
- Globules possibly from rapid decomposition of DMAB.
- Alloy formation from galvanic displacement of Co by Pt and re-deposition by ED (some of the Co dissolved in the bath).

PRIOR WORK: SEMI-CONTINUOUS ELECTROLESS DEPOSITION OF PLATINUM

- By not loading all of the ED reactants initially in the bath, high concentrations are avoided and the rate of deposition is slowed down.

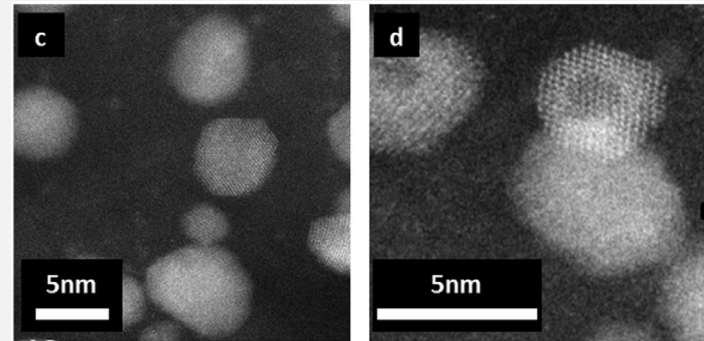

Precursor + stabilizer solution

Reducing agent solution

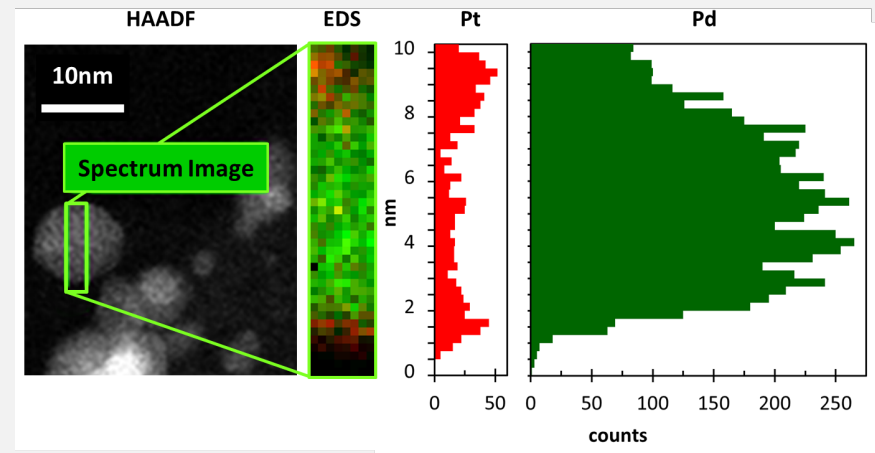

Base catalyst

Pt on Pd/C by semi-continuous ED
30% Pd/C as base catalyst

1.7 ML (11%) Pt

2.7 ML (17%) Pt

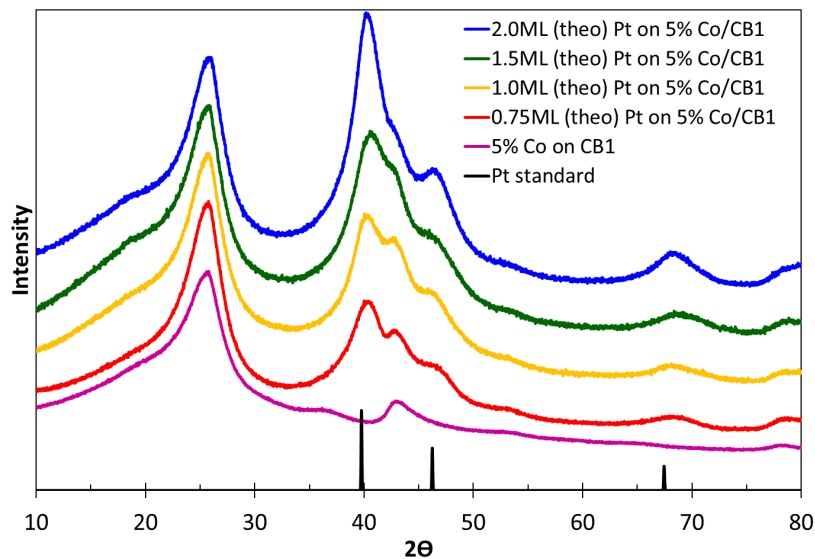

- Gradual addition of layers of secondary metal to higher loadings can be achieved.

APPLICATION OF SEMI-CONTINUOUS ED TO PLATINUM DEPOSITION ON CARBON SUPPORTED COBALT

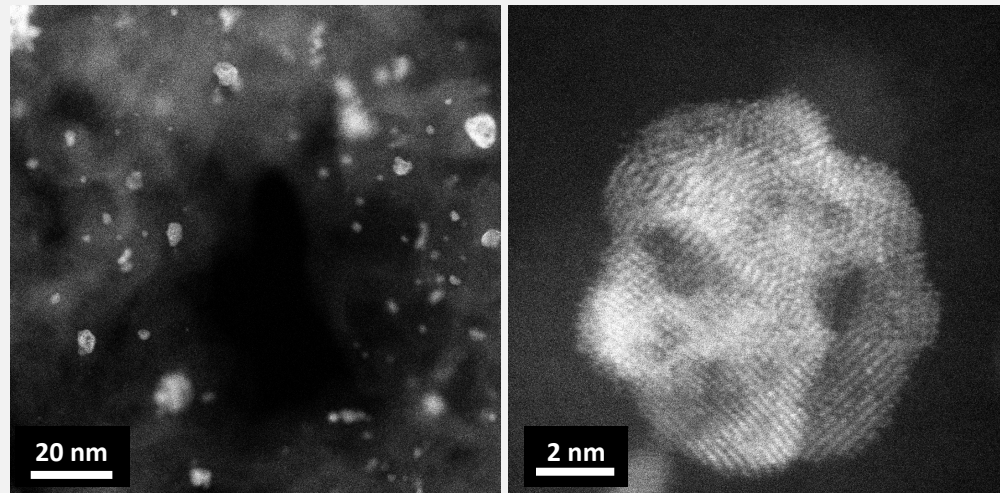

Akkarat Wongkaew, John Tengco, Yunya Zhang, John Regalbuto, John Monnier

- Same molar ratios of Pt precursor, EN stabilizer, and DMAB as batch system.
- Pt precursor and EN were pumped from a single reservoir while DMAB was added from another.

XRD patterns of Pt on Co/CB1 (Semi-Continuous ED)

Representative Dark Field Micrographs Pt-Co/CB1
1.5ML Pt - 5.0% Cobalt on Carbon Black, reduced 200°C, 1 hr

- FCC peaks corresponding to Pt-Co alloy phase with lattice contraction (relative to Pt) was observed for all samples.
- No observed hollow globule type particles.
- Aggregates of smaller particles were observed in STEM.
- Grains/particles were speckled in Z-contrast imaging, due to intermixing of Co with Pt.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

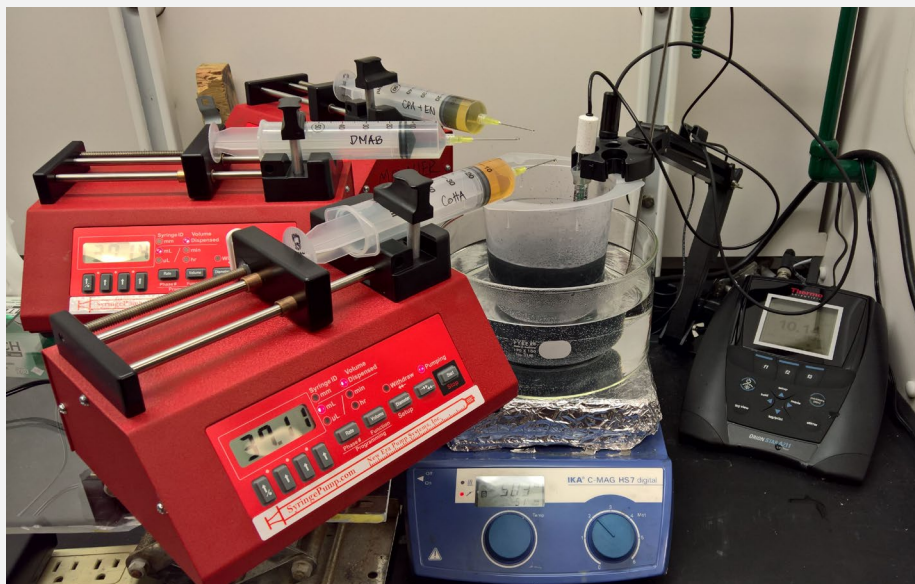

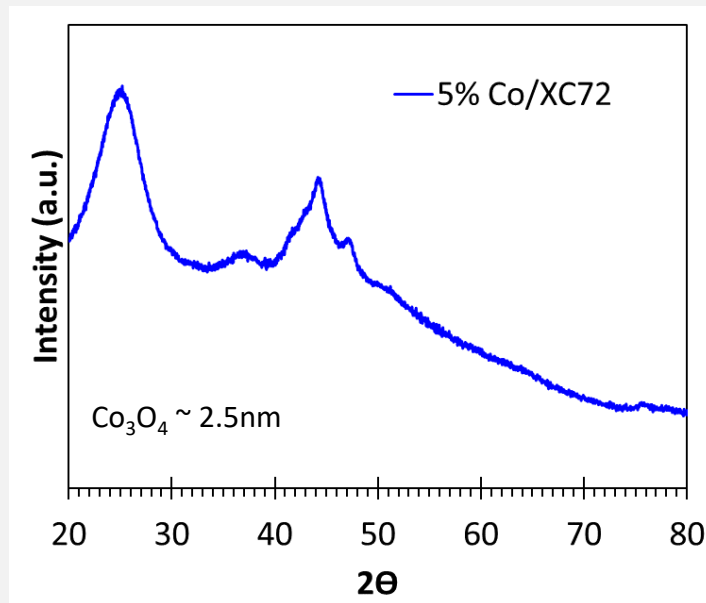

Base Co/C catalyst

- New base catalyst made on Vulcan XC72 carbon (BET SA = 250 m²/g)
- 5% Co loading prepared by same modified CEDI method, annealed in He at 250°C for 4hrs, reduced at 400°C for 1hr.

co-ED Reagents

- Reducing Agent (RA): Dimethylamineborane (DMAB)
- Pt Precursor: Chloroplatinic acid, H₂PtCl₆ (CPA)
- Co Precursor: Hexaminecobalt chloride (CoHA)
- Ethylenediamine (EN) added to Pt solution

XRD pattern of Co base catalyst

Semi-Continuous co-ED Parameters

Metal:RA = 1:5

Pt:EN = 1:4

Pt:Co = 3:1, 2:1, 1:1

Temp. = 50°C

pH = 10.0 to 10.5

Initial bath volume = 450 mL

CPA+EN volume = 50 mL

DMAB volume = 50 mL

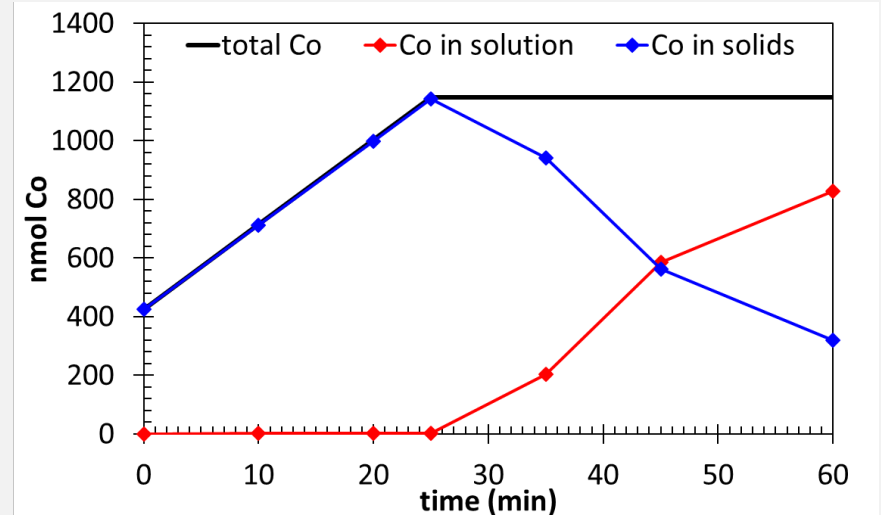

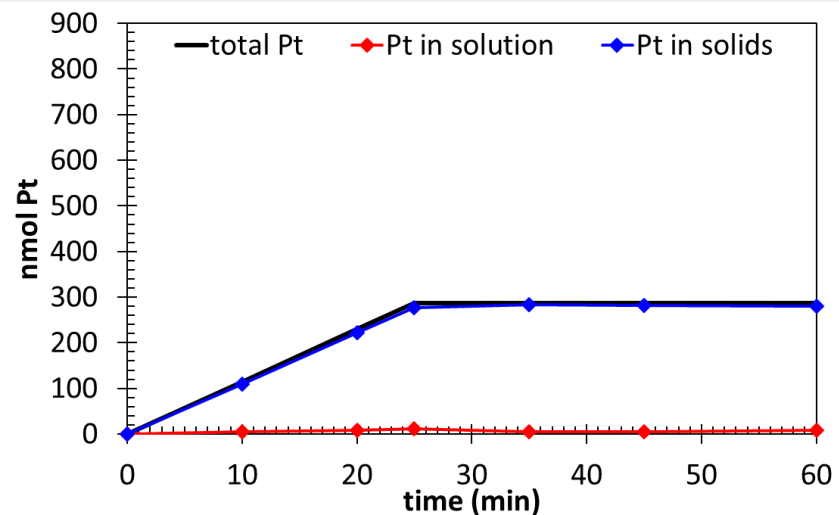

CoHA volume = 50 mL

Pump rate = 2 mL/min

Run time = 25 min pump + 35 min rest

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

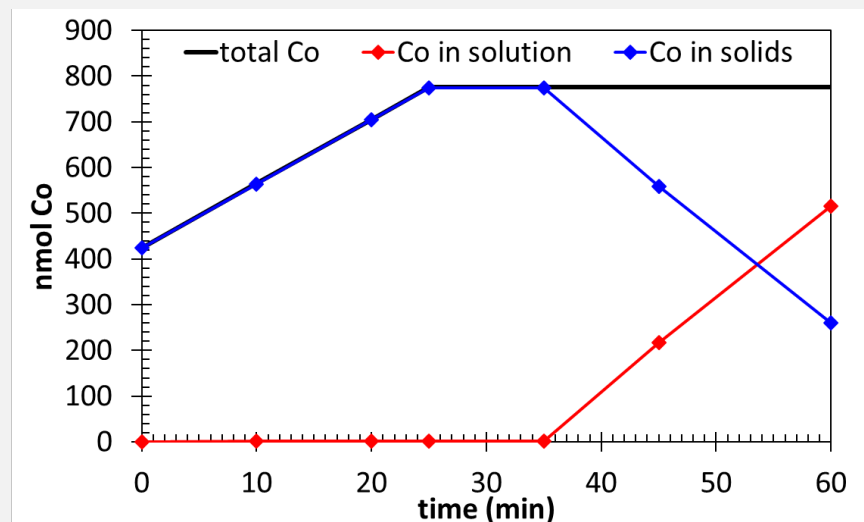

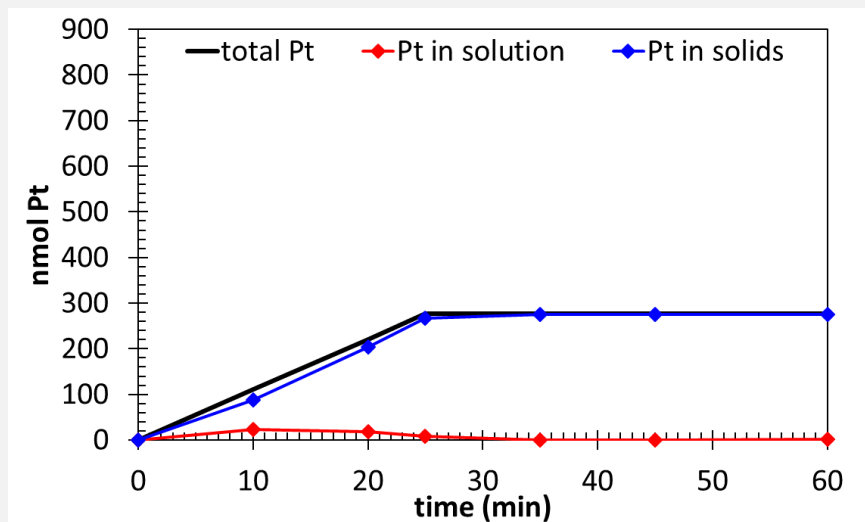

$Pt:Co = 1:3$

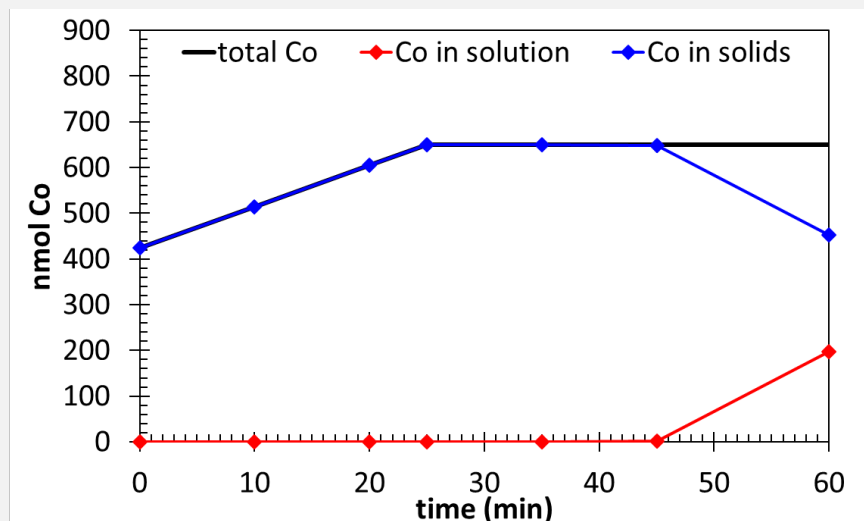

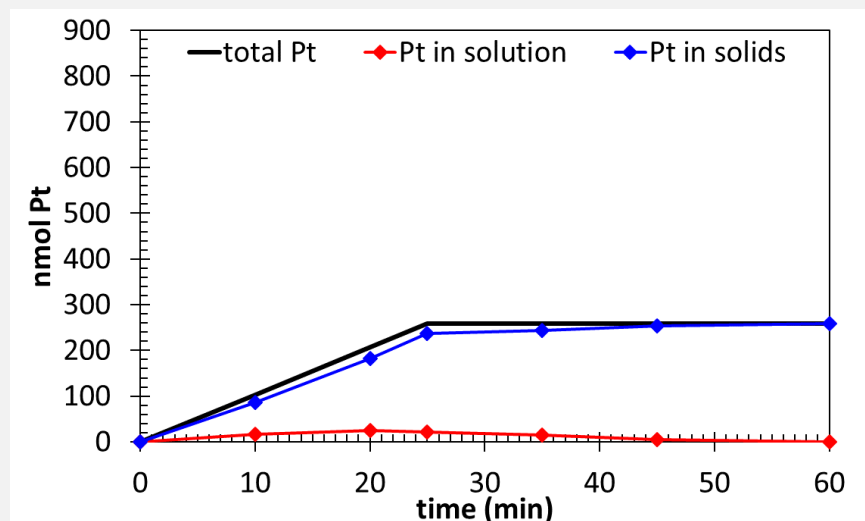

- Complete deposition of Pt was achieved, while Co deposition was complete during the pumping regime (25 min).
- Leaching of Co into solution after pumping of precursors and reducing agent has ended.
- More Co leaches out, eventually losing Co from the base catalyst.
- Increasing Pt:Co decreases Co leaching, possibly due to more corrosion resistant alloy being formed.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

$Pt:Co = 1:1.5$

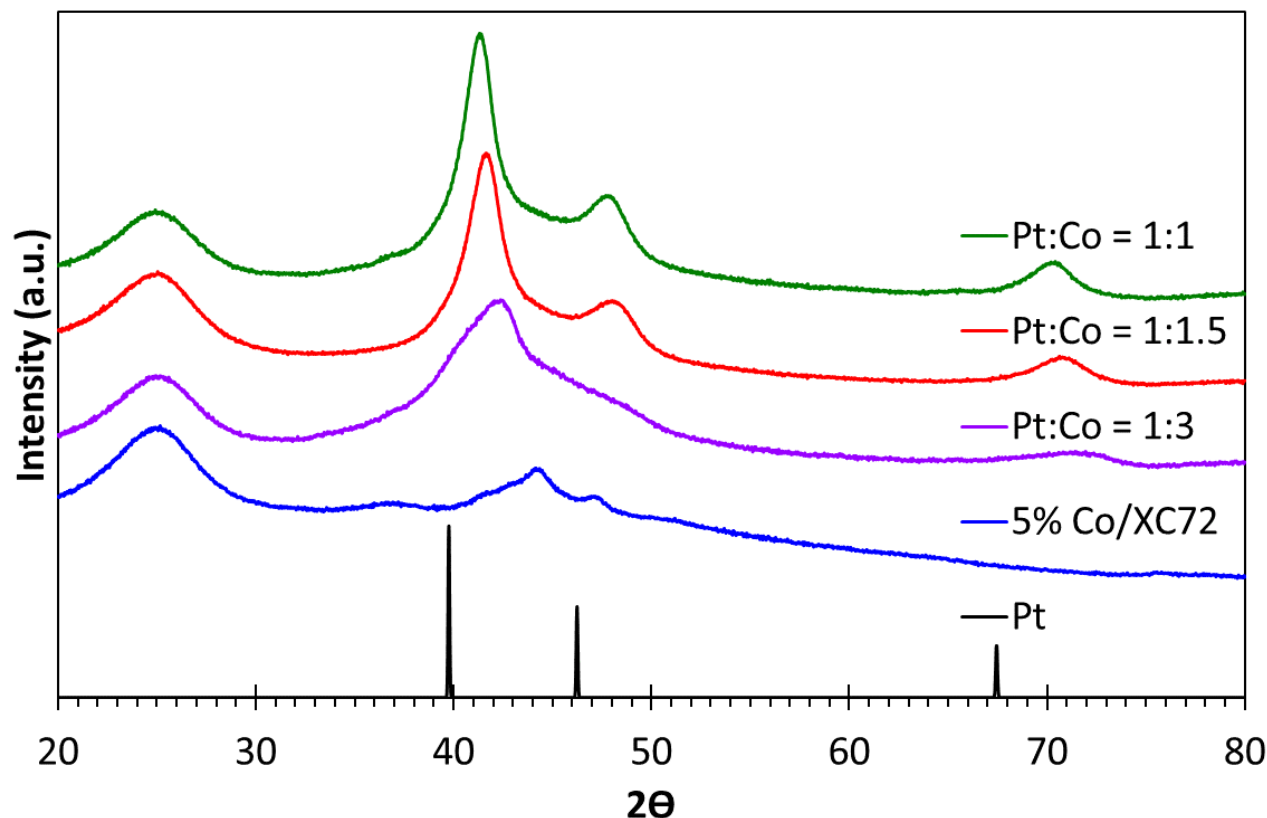

$Pt:Co = 1:1$

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

XRD patterns of co-ED prepared Pt-Co/C catalysts

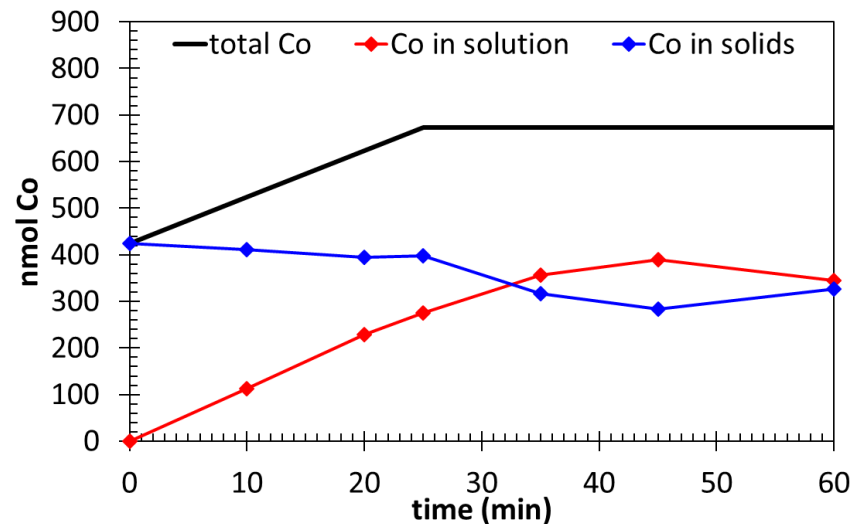

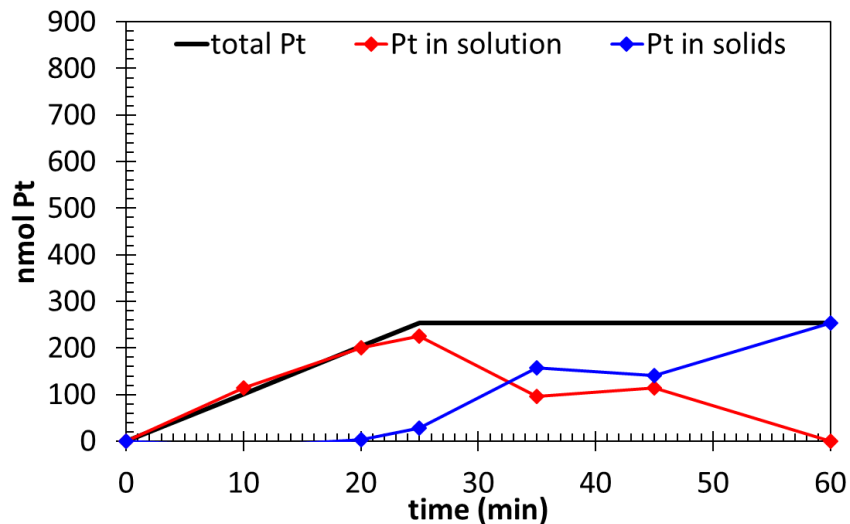

- FCC peaks corresponding to Pt-Co alloy phase with lattice contraction (relative to Pt) was observed for all samples.
- While all samples have resulting similar metal loadings, sample with feed ratio of Pt:Co = 1:1 gave the best dispersion based on XRD.
- Lattice parameter: 3.70 Å – 3.78 Å.
- Pending confirmation with STEM.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

Ethylenediaminetetraacetic Acid Disodium Cobalt as Precursor

$Pt:Co = 1:1$

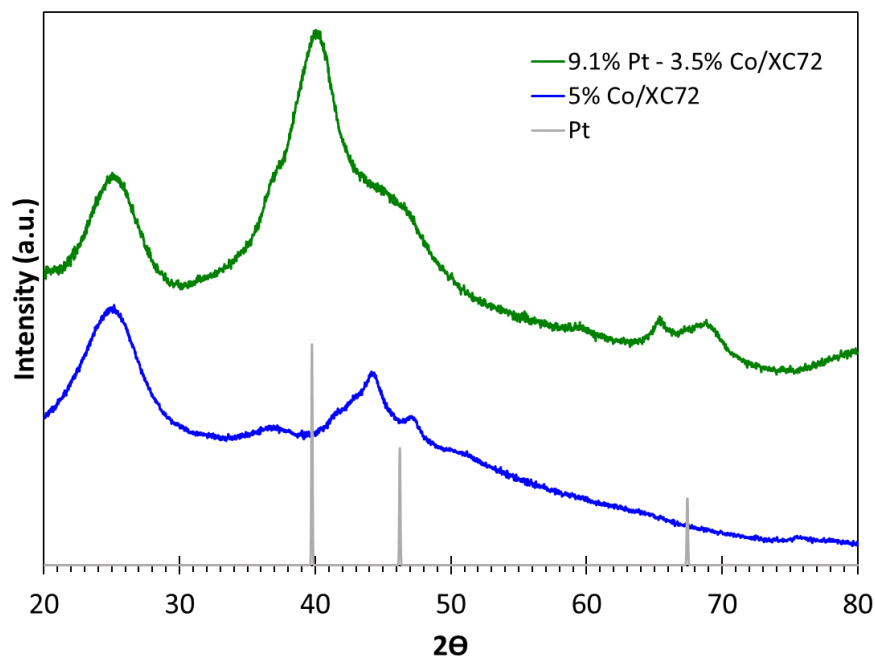

- CoEDTA complex substituted as precursor for Cobalt.
- Slower deposition of Pt was observed and virtually no net deposition of Co, possibly equal competing rates of displacement of Co (by Pt) and deposition.

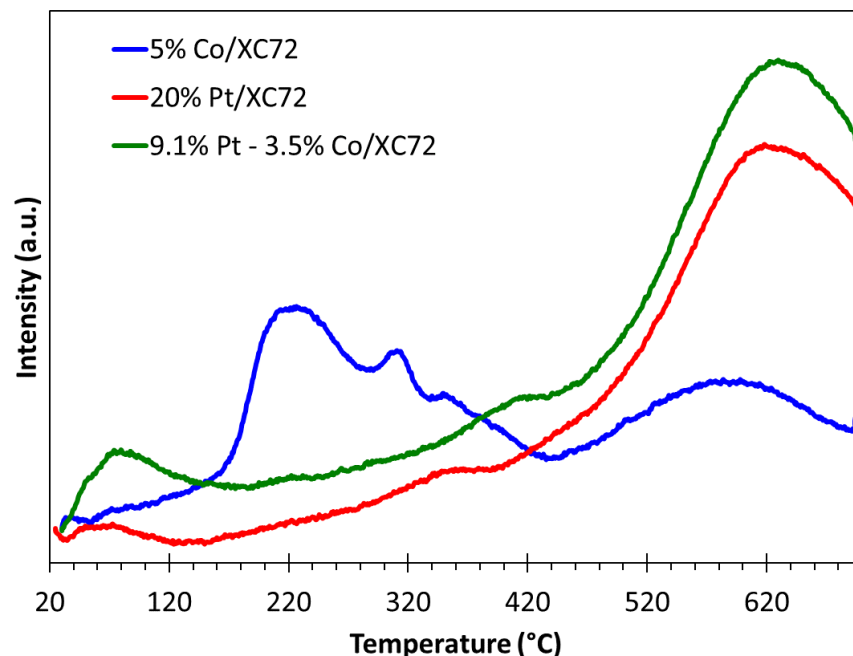

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

Ethylenediaminetetraacetic Acid Disodium Cobalt (CoEDTA) as Precursor

X-ray Diffraction

TPR of O-pre-covered catalysts

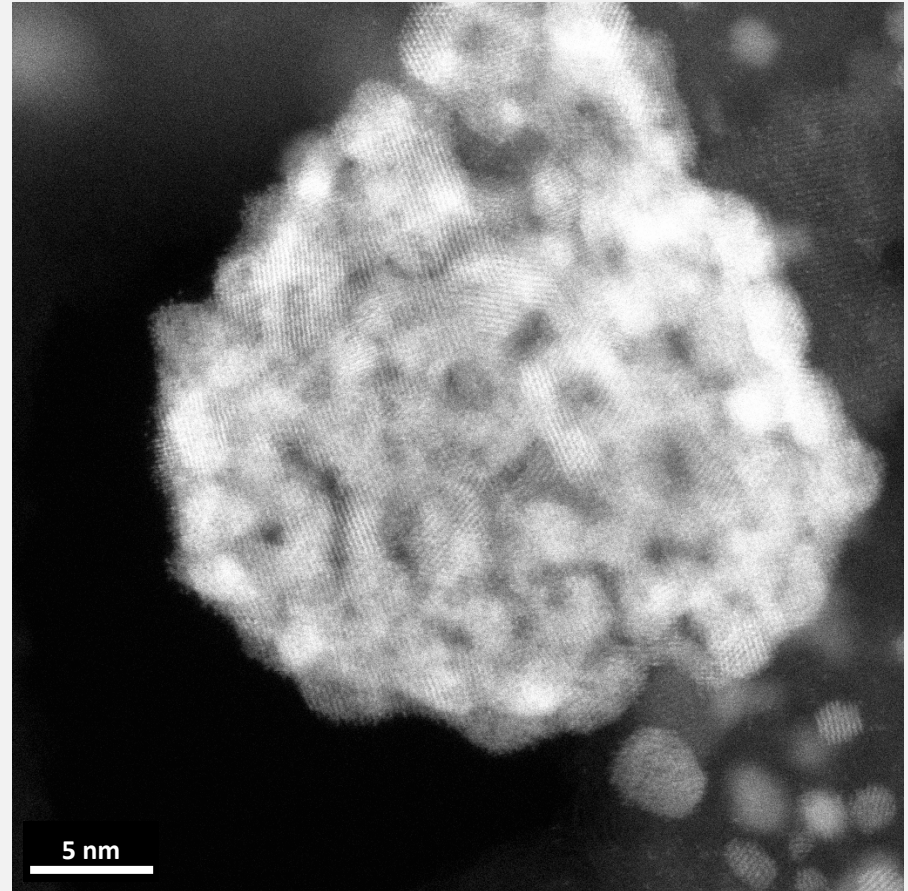

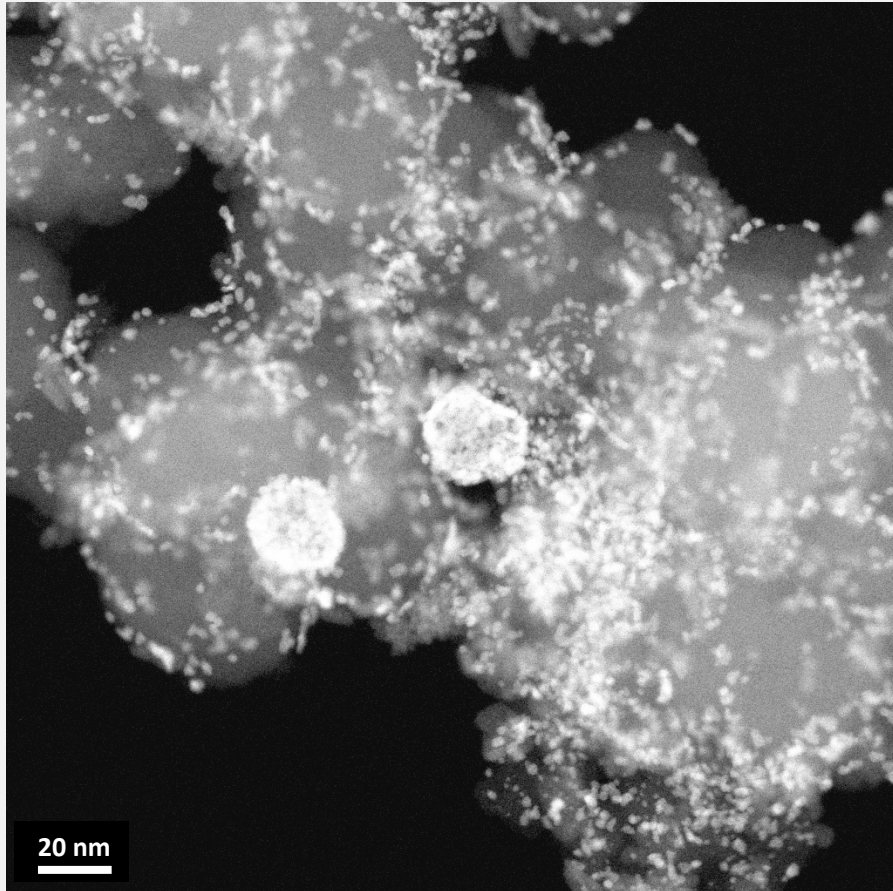

- XRD pattern still shows formation of well dispersed alloy nanoparticles (lattice parameter: 3.88 Å).
- TPR results indicate close contact between Pt and Co on the catalyst surface, resulting in lowering of reduction temperature due to Pt assisted reduction of surface Co-oxides.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

CoEDTA as Precursor

Representative Z-contrast Micrographs

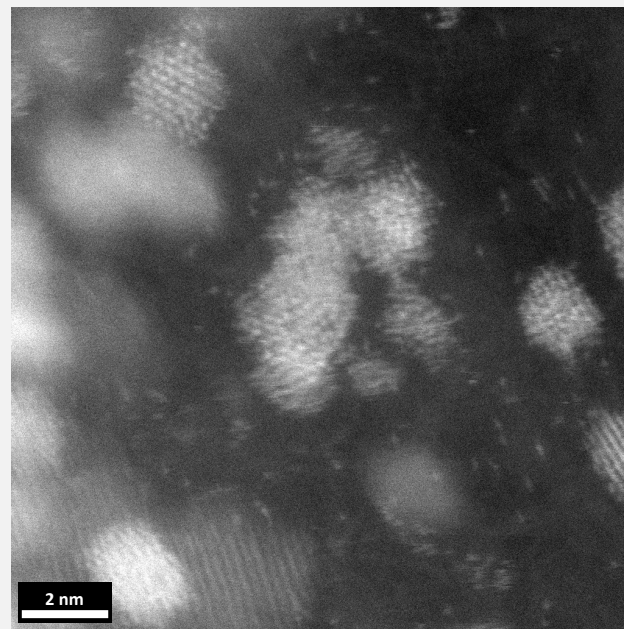

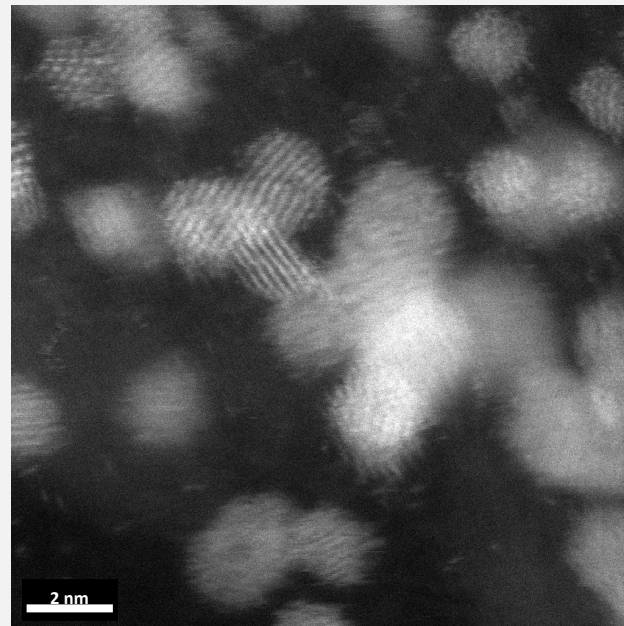

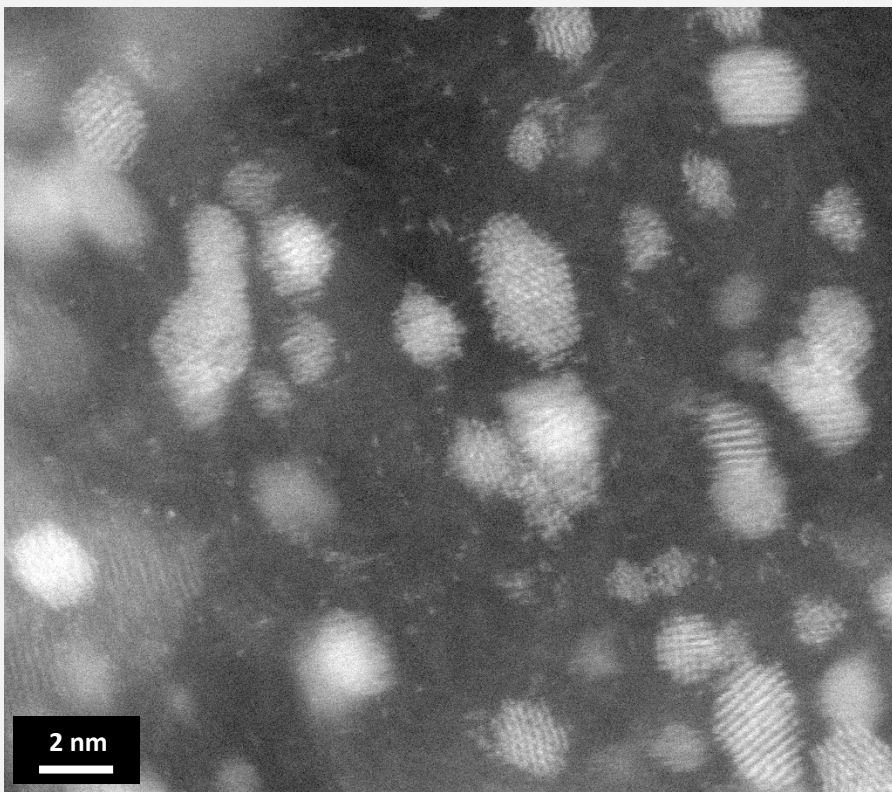

- Presence of agglomerated particles with distinct small grains.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

CoEDTA as Precursor

Representative Z-contrast Micrographs

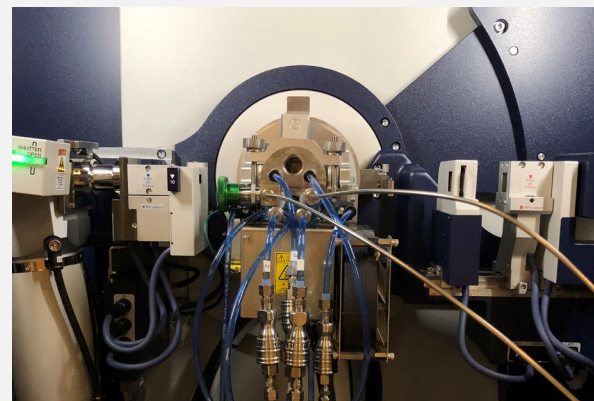

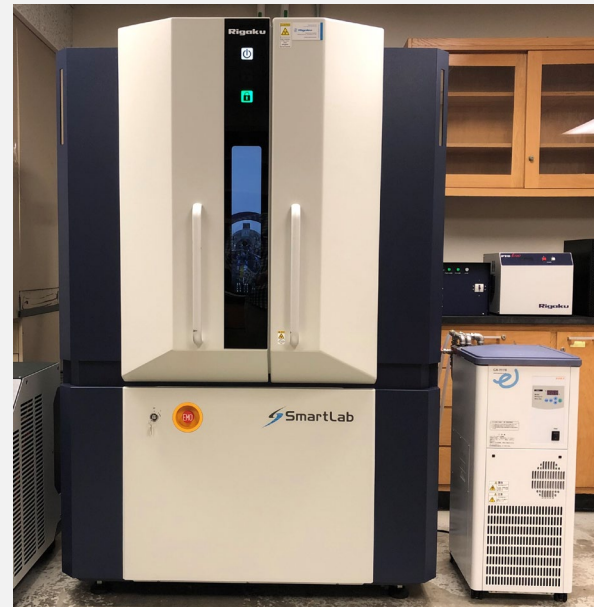

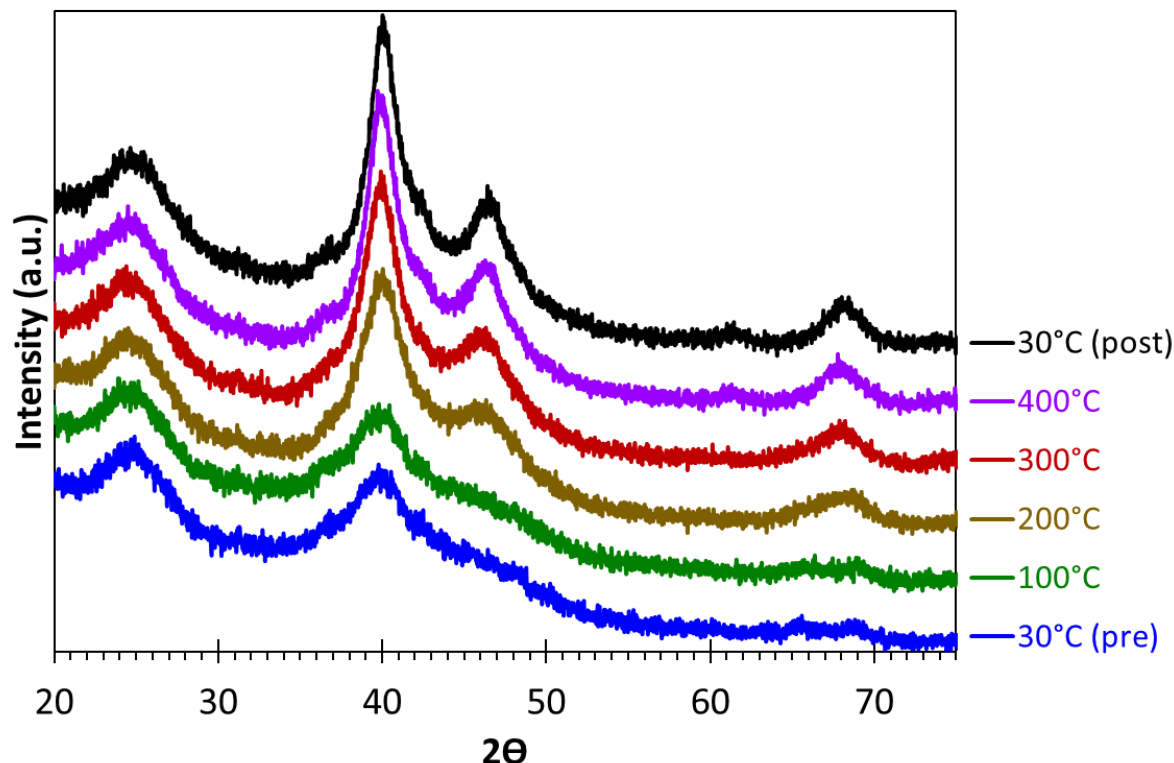

- Presence of dispersed single atom Pt.
- Speckling of nanoparticles (breaks in bright fringes) associated with alloy phase.

CO-DEPOSITION (co-ED) OF COBALT WITH PLATINUM

CoEDTA as Precursor

- In-situ XRD under N_2 flow using Rigaku Smartlab equipped with D/tex Ultra detector.
- $10^\circ\text{C}/\text{min}$ heat rate, 5 min equilibration time at dwell temperatures, $5^\circ/\text{min}$ XRD scan rate

- Alloy phase begins to sinter at 200°C .
- Shift towards higher 2θ observed – further mixing with Co or lattice rearrangement?

Planned Work

- Repeat co-ED experiments, ensuring correct Pt concentration (Pt:Co = 3:1)
- Prepare base catalyst with co-impregnation Co-citrate + CPA → alloyed base catalyst?
